

Figure 1 Flow chart of the identification of eligible studies.

in the roxadustat group, with a WMD of -52.93 (95% CI: -66.87 to -38.99, P < 0.00001), compared with those in the placebo group; while in the DD patients, there was no significant difference in the effect on ferritin level between the roxadustat group and the ESA group (WMD = -17.10, 95% CI: -46.71 to 12.52, P = 0.26; Fig. 4b).

Compared with the control group, roxadustat significantly increased the transferrin levels, with a WMD of 0.55 (95% CI: 0.41 to 0.69, P < 0.00001; Fig. 4c). A subgroup analysis showed that the transferrin levels were significantly different between the NDD and DD patients (P = 0.001; Fig. 4d). In the NDD patients, the results showed an increase in the transferrin levels, with a WMD of 0.69 (95% CI: 0.55 to 0.84, P < 0.00001), in the roxadustat group compared to the placebo group. Meanwhile, in the DD patients, the transferrin levels increased, with a WMD of 0.40 (95% CI: 0.30 to 0.50, P < 0.00001), in the roxadustat group compared to the ESA group.

Changes in hepcidin between groups

In the included studies, hepcidin levels were reported in 2227 subjects from the roxadustat group and 1608 subjects from the control group. The random effects model was used for meta-analysis and indicated that the reduction effect on hepcidin levels was more significant in the roxadustat group than in the control group, and the difference was statistically significant (WMD = -24.04, 95% CI: -36.28 to -11.79, P = 0.0001; Fig. 5a). As the data (P < 0.00001, $I^2 = 90\%$) indicated an obvious heterogeneity, we performed a subgroup analysis. A subgroup analysis showed

that the hepcidin levels were not significantly different between the NDD and DD patients (P = 0.13; Fig. 5b).

Changes in Hb between groups

Among 2724 patients treated with roxadustat and 2065 patients treated with placebo or ESA, a great heterogeneity was found in the Hb levels (P < 0.00001, $I^2 = 99\%$; Fig. 5c). The random effects model was used for meta-analysis and indicated that roxadustat significantly increases Hb levels (WMD = 0.77, 95% CI: 0.42 to 1.12, P < 0.0001; Fig. 5c). A subgroup analysis showed that the Hb levels were significantly different between the NDD and DD patients (P < 0.00001; Fig. 5d). In the NDD patients, the results showed an increase in the Hb levels, with a WMD of 1.82 (95% CI: 1.52 to 2.12, P < 0.00001), in the roxadustat group compared to the placebo group. Meanwhile, in the DD patients, the results also showed an increase in the Hb levels, with a WMD of 0.25 (95% CI: 0.08 to 0.42, P = 0.005), in the roxadustat group compared to the ESA group.

Changes in serum iron between groups

The SMD was used when iron units were inconsistent among the studies. In the included literature, 2668 patients were in the roxadustat group and 2036 patients were in the control group. Due to the low heterogeneity among included studies (P=0.13, $I^2=32\%$), the fixed effects model was used for meta-analysis and indicated that the increased effect of the serum iron levels in the roxadustat group was more significant than that in the control group (SMD = 0.21, 95% CI: 0.15 to 0.27, P<0.00001; Fig. 6a).

Author	Location	year	No. of patients (n)	Age (year)	Usage of iron	Baseline Hb	Roxadustat dose (g/day)	Study duration (week)	Patients type	control

Roxadustat safety

Next, we analyzed the extracted AEs and SAEs data to assess the safety of oral roxadustat. Among 2347 patients treated with roxadustat and 1585 patients treated with placebo or ESA, the incidence of AEs in the roxadustat group was significantly higher than that in the control group (RR = 1.03, 95% CI: 1.00 to 1.07, $I^2 = 10\%$, P = 0.04; Fig. 6b). Among 2869 patients treated with roxadustat and 2102 patients treated with placebo or ESA, the incidence of SAEs in the roxadustat group was significantly higher than that in the control group (RR = 1.08, 95% CI: 1.00 to 1.15, $I^2 = 0\%$, P = 0.04; Fig. 6c).

Discussion

To our knowledge, this study is a meta-analysis that specifically evaluated the efficacy of roxadustat on improving iron metabolism in NDD and DD patients with CKD. Twelve studies with 4976 patients met our inclusion criteria. Most selected studies were well-designed, but important information was missing from some reports, especially the generation of random sequences and allocation concealment, which might have led to bias.

Previous meta-analyses have shown that roxadustat can effectively improve renal anemia; however, few specific analysis of iron metabolism has been reported.^{11,12} In this

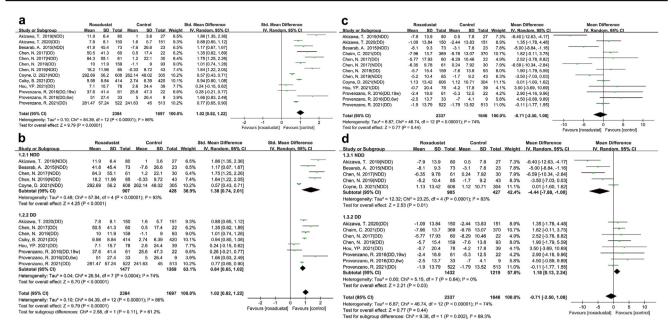

Figure 3 Forest plots for comparisons of total iron binding capacity (a) and transferrin saturation (c). Subgroup analysis of effect of roxadustat on outcome based on non-dialysis-dependent and dialysis-dependent patients: total iron binding capacity (b); transferrin saturation (d).

study, apart from Csiky B's study, other trials limited intravenous iron but allowed oral iron supplementation. Under these conditions, our meta-analysis showed that roxadustat increased the serum iron, increased TIBC and transferrin, and decreased ferritin and hepcidin. These findings showed that roxadustat could effectively increase the utilization of iron. In particular, in patients with functional iron deficiency, roxadustat can improve the absorption and utilization of iron and prevent the harm caused by iron overload. 13 Roxadustat is an orally bioavailable HIF—PHI that was the first to enter a phase III

clinical trial. ¹⁴ In this review, research of DD and NDD patients in different disease states may have been a source of bias. To reduce this risk, we performed a subgroup analysis of patients in both DD and NDD groups, which showed that TSAT was significantly reduced in the roxadustat group for NDD patients (P=0.01) and TSAT was significantly reduced in the ESA group for DD patients (P=0.03). Similarly, roxadustat significantly reduced ferritin levels compared with placebo in the NDD group (P<0.00001) and there no significant difference between roxadustat and ESA in the DD group (P=0.26), indicating

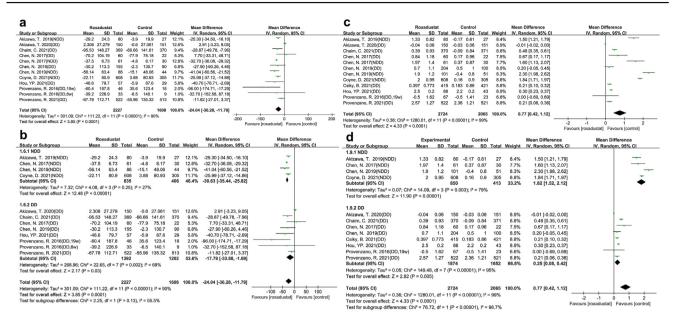

Figure 5 Forest plots for comparisons of hepcidin (a) and hemoglobin (c). Subgroup analysis of effect of roxadustat on outcome based on non-dialysis-dependent and dialysis-dependent patients: hepcidin (b); hemoglobin (d).

that the source of the heterogeneity of the data between the two groups was dialysis or non-dialysis. Hepcidin is a key factor in iron metabolism, which is affected by iron status, inflammation, and the oxygen concentration and can predict disease progression and mortality in patients with CKD. ¹⁵ Our meta-analysis showed a decrease in the hepcidin level, which indicated that roxadustat enhanced iron uptake and mobilization by reducing hepcidin levels. Consistently, a study has shown that reducing hepcidin concentrations can improve iron homeostasis and anemia in renal animal models. ¹⁶

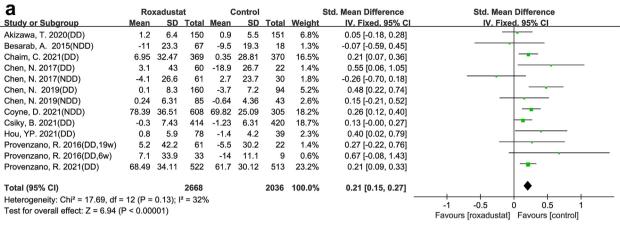

The HIF oxygen-sensing pathway is considered an important pathway for iron homeostasis.¹⁷ HIF binds directly to hypoxia response elements in DNA¹⁸ and regulates the expression of iron-related proteins. HIF-1 induces the expression of transferrin, transferrin receptor 1, and ceruloplasmin to improve iron utilization, while HIF-2 regulates divalent metal-regulatory protein 1 and duodenal cytochrome b and reduces the trivalent iron ion to the ferrous ion for absorption by intestinal cells. 19 A recent study on HIF- 2α knockout mice also showed that the HIF played a critical role in iron absorption and utilization.²⁰ Compared with the DD patients, the NDD patients with CKD showed a greater reduction in hepcidin levels and a greater increase in transferrin, suggesting a better iron metabolism in the latter patients, which may be related to their residual renal function.

Long-term use of HIF-PHIs may have AEs due to persistent activation of HIF-regulated genes. In particular, the activation of vascular endothelial growth factor is involved in various biological processes, such as cell differentiation, mitochondrial metabolism, and tumor growth. However, in a phase III study in Japan, 22 the incidences of new or worsening retinal hemorrhages were similar between the darbepoetin alfa and roxadustat groups, and no clinically significant changes were found in the retinal

thickness. AEs and SAEs are considered major challenges in clinical application of roxadustat. A recent study of pooled RCTs in NDD patients, with a noninferior study design, reported roxadustat is noninferior to placebo with respect to MACE. ²³ And in DD patients, roxadustat was non-inferior to ESA for risks for MACE and MACE+. ²⁴ However, FDA Roxadustat Briefing Document of Roxadustat (NDA 213805) released on July 15, 2021 reported that roxadustat may increase the risk of thrombosis and even mortality. In our included studies, the incidences of AEs and SAEs were significantly increased in roxadustat group, which indicates that the roxadustat has higher risks than ESA. Therefore, larger and longer follow-up studies are needed to discover and confirm its safety in clinical use.

To ensure the quality of the study, we only included RCTs. Nevertheless, our research has some limitations. First, the limited number of studies may affect the strength of meta-analysis. Second, due to the relatively short duration of selected studies, the long-term efficacy of roxadustat cannot be predicted, and the long-term incidence of AEs and SAEs cannot be obtained. Third, although we did a subgroup analysis, several results had high heterogeneity. This may be related to the baseline patient characteristics, the differences in roxadustat and iron dosages, the differences of baseline iron parameters and treatment durations in the included studies.

In this study, we investigated the therapeutic effectiveness of roxadustat in the treatment of iron metabolism disorders in NDD and DD patients with CKD using a meta-analysis. In general, roxadustat could increase iron bioavailability via enhanced intestinal iron absorption and release of iron from functional storages by improving TIBC and transferrin, and reducing hepcidin levels. From a clinical perspective, roxadustat is especially useful for patients with renal anemia with functional iron deficiency.
